there are no commercially-available prototyping tools that we know of, that allow the creation of an interactive prototype that is keyboard and screen-reader accessible

how can we create accessible prototypes most efficiently?

we looked at the possibility of hacking the output from Adobe CC XD, but this seems unfeasible, as they output the screens just as images with active touch areas

best would probably be to build from scratch (html/css/javascript), but simplify the interactions and flows to be more efficient in our prototyping process

this might be advantageous also because we would be able to build on what we have for the prototype when implementing the “shipped product”

for now, on the privacy project, we’ll proceed with creating a prototype in CC XD, and will consider how we can make the testing process accessible (e.g. by providing active screen-reading or screen-touching for the user)
